MIS 430 Final Project Deliverables

See slide deck for assignment details

Final Project Deliverables:

Note that this is everything your team turns in. You will build a lot of it gradually across the group phase of the project. Your weekly status reports track progress on each, and TAs can review drafts in office hours before the final due date

1. **Elicitation Report**

   This is the report your team will put together based on the information gained from the interviews you conduct with real potential users. Details are outlined in the assignment document, and this should include who you talked to, why you chose those individuals, what you learned, and how what you learned shaped your work moving forward.

2. **Statement of Work (SOW)**

   This is your project's defining document. This clearly outlines the problem (grounded in your fieldwork), scope, prioritized requirements, deliverables, roles, risks, and reporting plan. The SOW should use the provided template. This will be submitted earlier in the group work phase and graded with feedback that should be incorporated into the final deliverable version.

3. **Process Models: current and future state**

   These are swimlane/process diagrams (as practiced earlier in the semester) showing both the process surrounding your product in its current state, and the process once your solution is implemented. Make sure you clearly show what your product actually changes.

4. **Data Model: future state**

   This is an ER-style data model (as practiced earlier in the semester) underlying your product. You must include key entities, attributes, and relationships, with any consequential assumptions noted.

5. **Product Backlog & First Sprint**

   The product backlog includes your prioritized user stories ("As a… I want… so that…"), each MoSCoW-ranked, with your Must-haves estimated (story points or t-shirt sizing) and a one-line reasoning each. Your first sprint is laid out from the top of the backlog, with a short justification of what you pulled in and what you deferred (scope, dependencies). Note that this must include at least one AI-feature user story.

   Acceptance criteria are required for all first-sprint stories and for your product's core AI feature, wherever it sits in the backlog. (As we worked on previously in the semester,

observable-condition criteria is preferred, and include what the AI does when it can't or shouldn't answer.)

6. Harm & Guardrail Analysis

This analysis outlines how your product could cause harm, and the guardrails (design decisions) that address it. This should include harm categories ranked by severity for your product, with proportional safeguards (as practiced earlier in the semester).

7. User Testing Plan & Results

Your plan for validating the design with real users, and what you learned from running it.

- *The plan (built in class, refined after)*: include goals, target users, 2-4 tasks (phrased as non-leading), what you'll measure/observe (including at least one trust-calibration observation), success criteria, and how you'll use results.
- *The results (after testing)*: These results should show who you actually tested with, what happened on each task (success/struggle/failure), what surprised you, what you'd change, and an honest statement of what you *couldn't* test (AI behavior/accuracy on a mockup). Note that this will be graded on honest findings and translation to action — not on whether the design "passed."

8. Change Management Plan

This is your plan plan for how the product's introduction would be managed, including rollout, adoption, resistance, and transition.

- *Stakeholder Impact & Strategy Analysis:* Provide analysis of 4 stakeholders (at least 1 who benefits, at least 1 who resists), each analyzed for how the change affects them (work, gains, losses, likely response) and given a tailored strategy (their concerns, how to communicate, how to involve them, support needs). This should be grounded in real fieldwork stakeholders where possible. Make sure this analysis addresses the AI-trust dimension for at least the key resister.
- *One-Page Rollout Plan:* Produce a visual one-pager outlining your rollout plan. Be sure to include who to engage first, communication approach/timeline, top adoption risks, how success is measured. This should be visual and concise; plain paragraph-style docs don't earn full credit).

9. BMAD Decision Log

This is your team's running record of where you changed, overrode, or rejected BMAD's output, and why. Note that this should be compiled from what you documented in each weekly status report, so you should not be generating new information for this deliverable.

10. Interactive Mockup

This is your “final product”, a clickable/navigable mockup of your product's key screens, demonstrating your core feature. Remember that building working AI is not required; the mockup represents the intended experience.

11. Final Presentation

Your team presents your work to the class.
